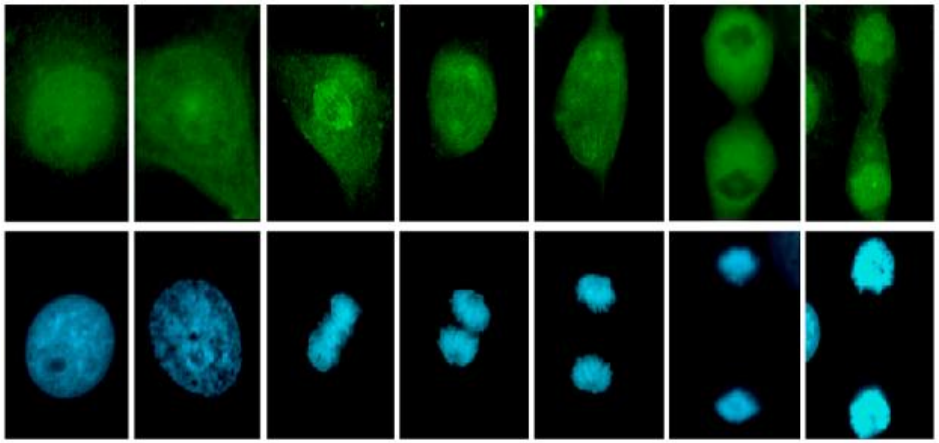
Part I: Background

The Ran (Ras-like Nuclear) GTPase

1. a member of Ras superfamily/small GTPase superfamily

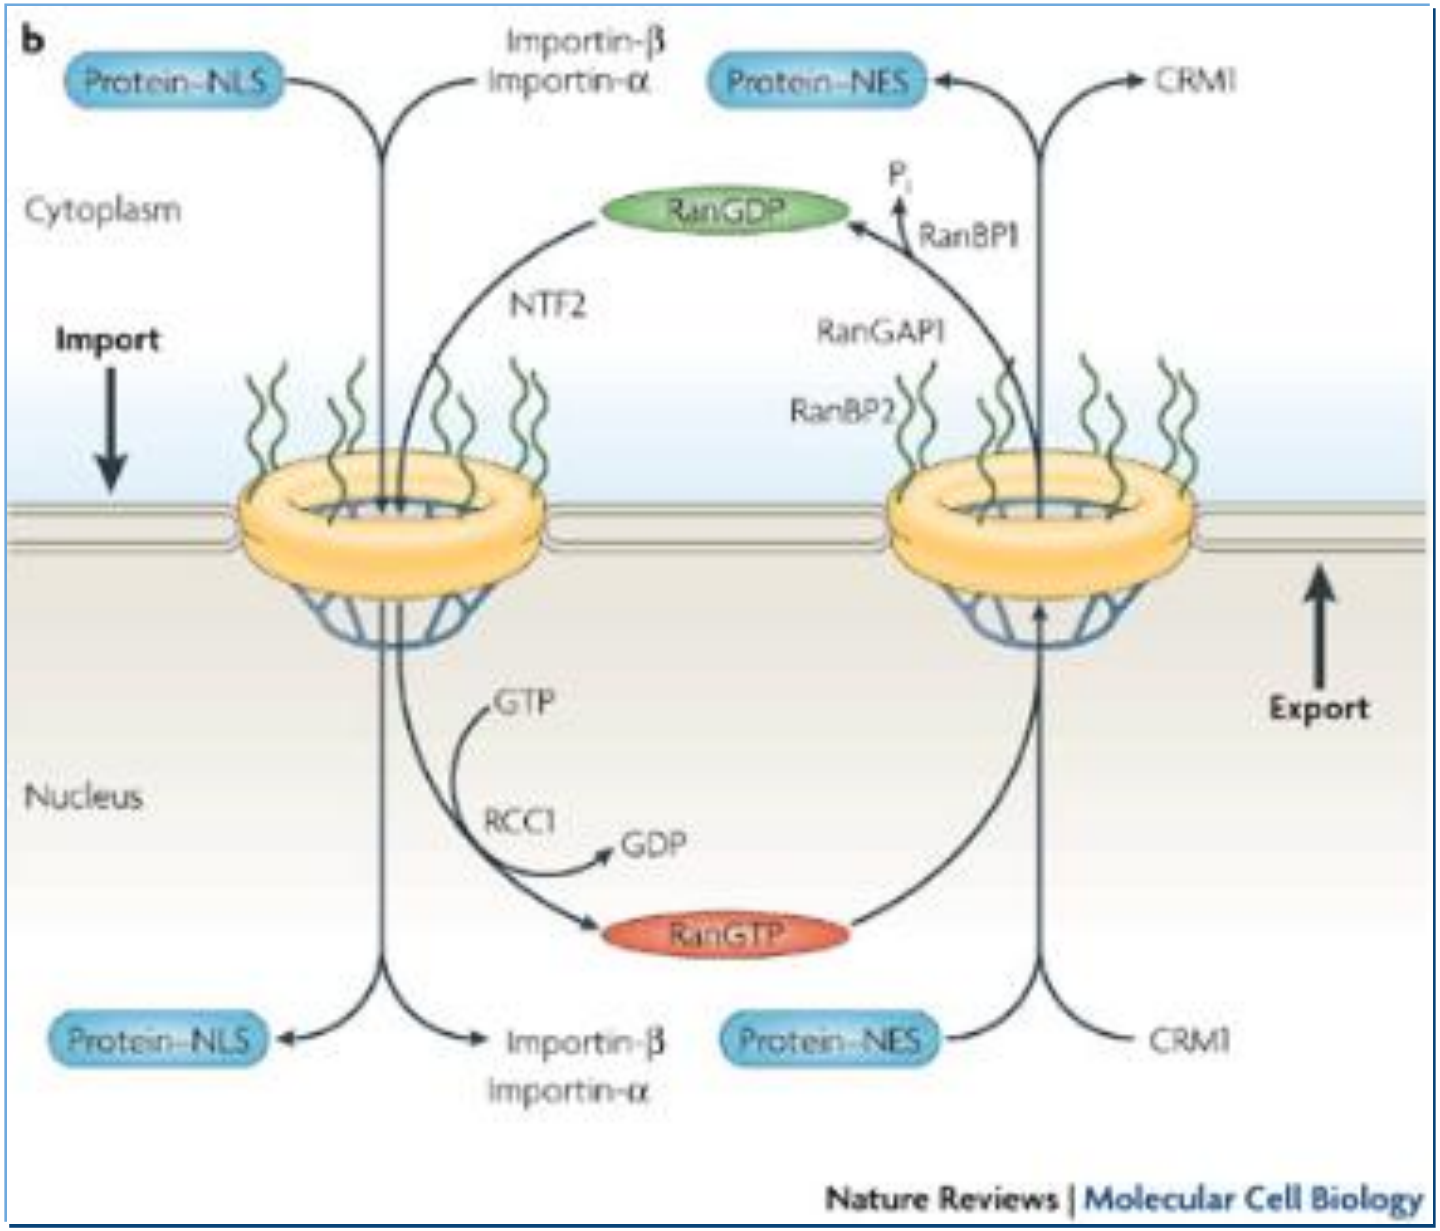
2. nuclear localization



3. very conservative (from yeast to human)

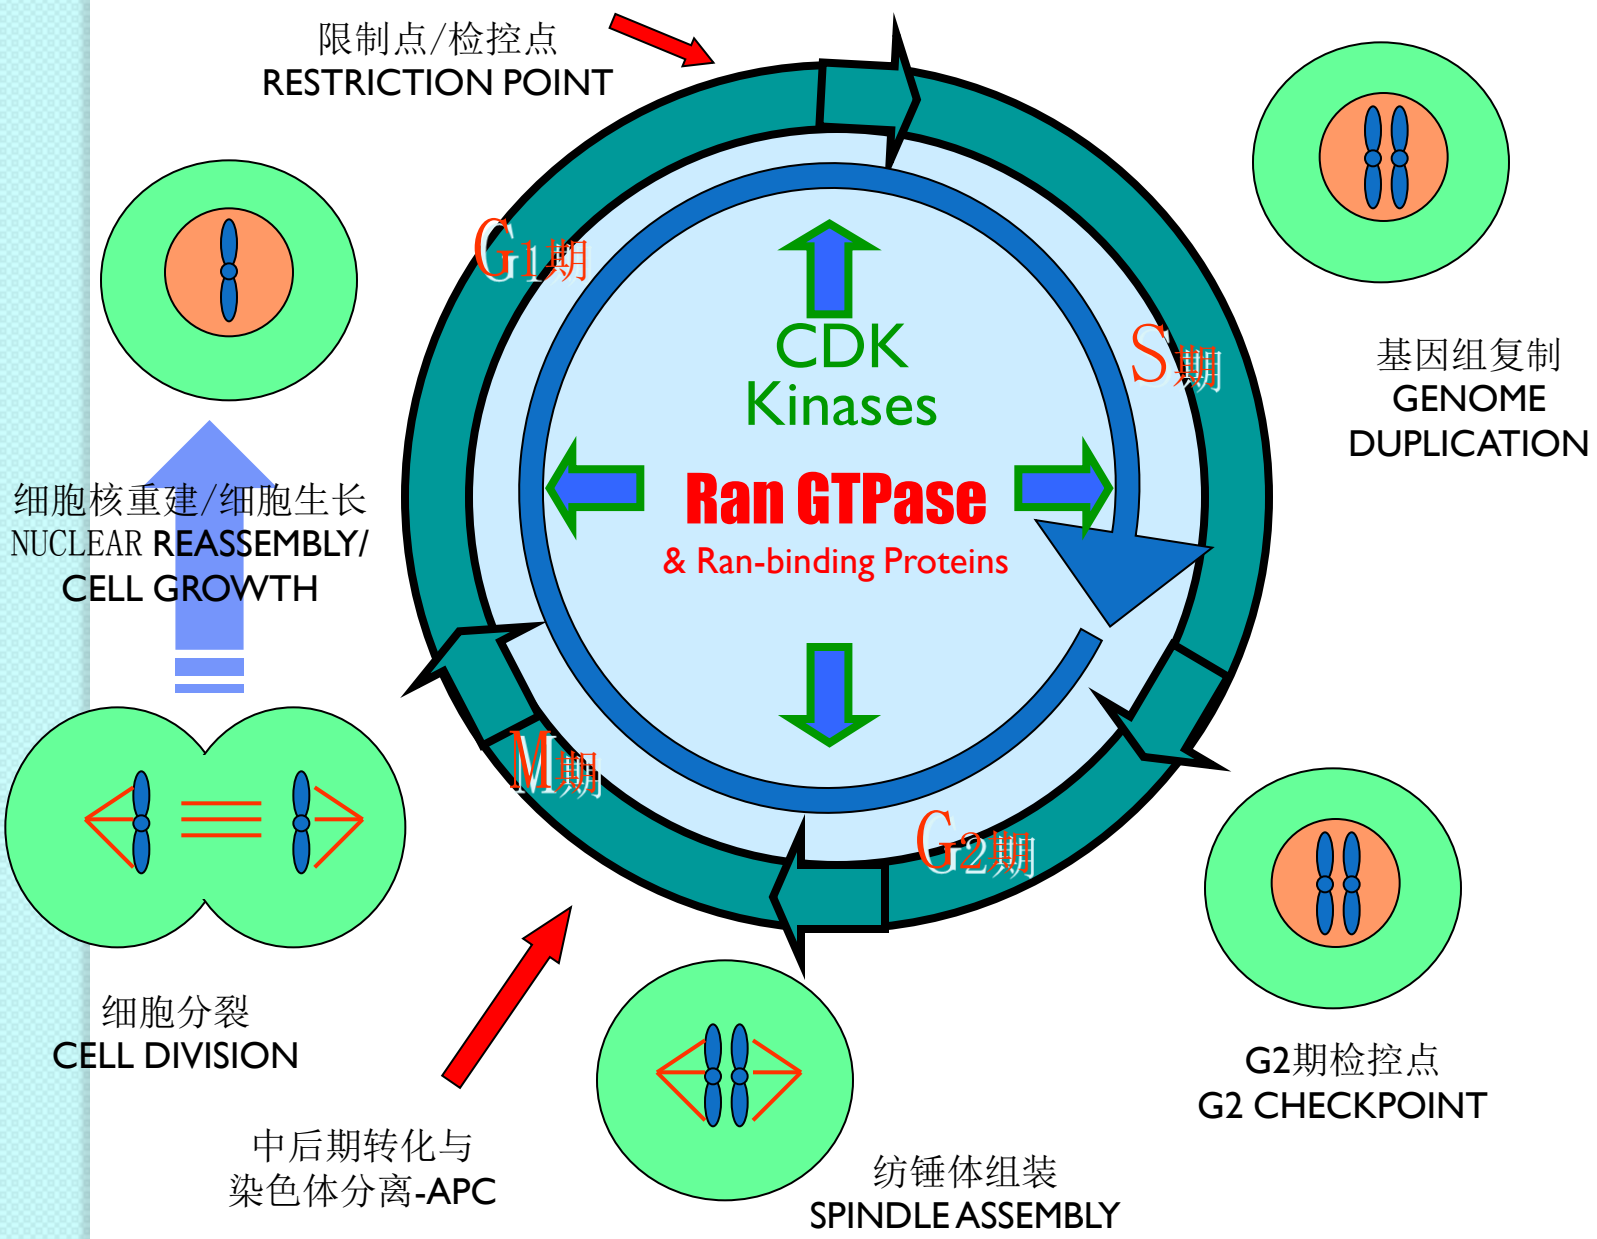
4. molecular weight, ~25Kd

5. GTPase activity



Nature Reviews Molecular Cell Biology **9**, 464-477 (June 2008)

A typical eukaryotic cell division cycle



Part II: Bioinformatic analysis of Ran

Ran (Human)

- Ref seq No.(mRNA) : NM_006325.3
- Gene Location:12q24.3
- Ref seq No.(Protein) : NP_006316.1
- Uniprot ID: P62826
- Protein length: 216AA
- No other isoforms in human
- Highly conservation

Results of Uniref100

Ciliary entry of the kinesin-2 motor KIF17 is regulated by importin-beta2 and RanGTP.

Department of Cell and Developmental Biology, University of Michigan Medical School, Ann Arbor, Michigan 48109, USA.

Abstract

The biogenesis, maintenance and function of primary cilia are controlled through intraflagellar transport (IFT) driven by two kinesin-2 family members, the heterotrimeric KIF3A/KIF3B/KAP complex and the homodimeric KIF17 motor. How these motors and their cargoes gain access to the ciliary compartment is poorly understood. Here, we identify a ciliary localization signal (CLS) in the KIF17 tail domain that is necessary and sufficient for ciliary targeting. Similarities between the CLS and classic nuclear localization signals (NLSs) suggest that similar mechanisms regulate nuclear and ciliary import. We hypothesize that ciliary targeting of KIF17 is regulated by a ciliary-cytoplasmic gradient of the small GTPase Ran, with high levels of GTP-bound Ran (RanGTP) in the cilium. Consistent with this, cytoplasmic expression of GTP-locked Ran(G19V) disrupts the gradient and abolishes ciliary entry of KIF17. Furthermore, KIF17 interacts with the nuclear import protein importin-beta2 in a manner dependent on the CLS and inhibited by RanGTP. We propose that Ran has a global role in regulating cellular compartmentalization by controlling the shuttling of cytoplasmic proteins into nuclear and ciliary compartments.

A size-exclusion permeability barrier and nucleoporins characterize a ciliary pore complex that regulates transport into cilia.

Kee HL, Dishinger JF, Blasius TL, Liu CJ, Margolis B, Verhey KJ.

Department of Cell and Developmental Biology, University of Michigan Medical School, Ann Arbor, Michigan 48109, USA.

Abstract

The cilium is a microtubule-based organelle that contains a unique complement of proteins for cell motility and signalling functions. Entry into the ciliary compartment is proposed to be regulated at the base of the cilium. Recent work demonstrated that components of the nuclear import machinery, including the Ran GTPase and importins, regulate ciliary entry. We hypothesized that the ciliary base contains a ciliary pore complex whose molecular nature and selective mechanism are similar to those of the nuclear pore complex. By microinjecting fluorescently labelled dextrans and recombinant proteins of various sizes, we characterize a size-dependent diffusion barrier for the entry of cytoplasmic molecules into primary cilia in mammalian cells. We demonstrate that nucleoporins localize to the base of primary and motile cilia and that microinjection of nucleoporin-function-blocking reagents blocks the ciliary entry of kinesin-2 KIF17 motors. Together, this work demonstrates that the physical and molecular nature of the ciliary pore complex is similar to that of the nuclear pore complex, and further extends functional parallels between nuclear and ciliary import.
